

## Probability & Inference

- Result of tossing a coin is  $\in \{H, T\}$

- Random variable  $X \in \{1, 0\}$

— Recall the Bernoulli PMF

$$P(X=1) = \theta^x (1-\theta)^{(1-x)}$$

- Sample:  $X = \{X^t\}_{t=1}^N$

- Estimation (MLE):  $\hat{\theta} = \frac{\# H}{\# \text{Tosses}} = \frac{1}{N} \sum_{t=1}^N X^t$

- Predict the next toss:

— if  $\hat{\theta} > \frac{1}{2}$ , T otherwise

NB: Notes based

Alpaydin chp 3

Bayesian Decision Theory

(1)

Conjugate Bayes

$$\theta \sim \text{Beta}(a, b)$$

$$\theta | X \sim \text{Beta}(a^*, b^*)$$

$$a^* = a + N_1$$

$$b^* = b + N_0$$

where  $N_1 = \# \text{heads}$   
 $N_0 = \# \text{tails}$   
 $N_0 + N_1 = N \# \text{of trials}$

## Classification

- Credit scoring: Inputs are income and savings

– output: low-risk vs high-risk

- Input:  $X = [x_1, x_2]^T$

Output:  $C \in \{0, 1\}$

- Prediction

choose/select  
or

$$\begin{cases} C=1 & \text{if } P(C=1 | x_1, x_2) > 0.5 \\ C=0 & \text{otherwise} \end{cases}$$

choose/select

$$\begin{cases} C=1 & \text{if } P(C=1 | x_1, x_2) > P(C=0 | x_1, x_2) \\ C=0 & \text{otherwise} \end{cases}$$

# Bayes' Rule

(3)

NB:

$$\left\{ \begin{array}{l} P(C=0|x) + P(C=1|x) = 1 \end{array} \right.$$

Posterior

likelihood

Prior

$$P(C|x) = \frac{P(x|C) P(C)}{P(x)}$$

the "evidence" or marginal of the data

Decision

choose  $C=1$  if

$$P(C=1|x) > P(C=0|x)$$

Prior prob.  $P(C=1)$  : prob. of high-risk customer

$$- P(C=0) + P(C=1) = 1$$

Class Likelihood:  $P(x|C)$  prob. of event belonging to class  $C$  given the observable  $x$  (Q: how ~~likely~~ likely are the data if the true state of the world is  $C$ )

-  $P(x_1, x_2 | C) =$  prob. that high-risk customer will have  $[x_1, x_2]^T$

Evidence:  $P(x)$  : marginal prob. of  $[x_1, x_2]^T$   $\left\{ \begin{array}{l} P(x) = P(x|C=1)P(C=1) + P(x|C=0)P(C=0) \end{array} \right.$

# Bayes' Rule for $k > 2$ Classes (mutually exclusive & exhaustive)

Posterior Prob  
↓

$$P(C_i | x) = \frac{P(x | C_i) P(C_i)}{P(x)}$$

$$= \frac{P(x | C_i) P(C_i)}{\sum_{k=1}^k P(x | C_k) P(C_k)}$$

Prior Probabilities :  $P(C_i) \quad \forall i=1, \dots, k$

$$\sum_{i=1}^k P(C_i) = 1$$

Class Likelihood :  $P(x | C_i)$

Decision:

Choose as the output the class  $C_i$   
that has the maximum posterior prob.

$$P(C_i | x)$$

## Losses and Risks

5

- Credit scoring decisions should be made so as to maximize gains / limit losses
- Classes  $C_1, \dots, C_k$
- Let  $d_i$  = decision to assign  $C_i$  to the input  $\forall 1 \leq i \leq k$
- Let  $\lambda_{ik}$  = the loss from assigning  $C_i$  to input that belongs to  $C_k$  (i.e. misclassification)
- Expected risk for  $d_i$ :

$$R(d_i | x) = \sum_{k=1}^k \lambda_{ik} P(C_k | x)$$

- Decision: choose  $d_i$  with minimal expected risk

$$R(d_i | x) = \min_k R(d_k | x)$$

## 0/1 Loss Case

- Correct decisions have 0 loss  
Incorrect decisions have 1 loss

$$\lambda_{ik} = \begin{cases} 0 & \text{if } i=k \\ 1 & \text{if } i \neq k \end{cases}$$

NB:

- all equal
- losses are symmetric

- The risk of taking action  $\alpha_i$  is:

$$R(\alpha_i | x) = \sum_{k=1}^K \underset{\substack{\uparrow \\ 0 \text{ or } 1}}{\lambda_{ik}} P(C_k | x) = \sum_{\substack{k=1 \\ k \neq i}}^K P(C_k | x) = \underbrace{1 - P(C_i | x)}_{\text{via complement rule}}$$

- Decision: to minimize risk, assign  $C_i$  to the most probable class

## Losses $\Rightarrow$ Risks: Reject

- misclassification: very high cost

- Consider an extra option  $(K+1)$ -st class "reject"

- Loss function:

$$\lambda_{ik} = \begin{cases} 0 & \text{if } i = k \\ \lambda & \text{if } i = k+1, \quad 0 < \lambda < 1 \\ 1 & \text{if } i \neq k \text{ and } i \neq k+1 \end{cases}$$

- Risk of reject:

$$R(d_{k+1} | x) = \sum_{k=1}^K \lambda P(c_k | x) = \lambda$$

- Risk of misclassification:

$$R(d_i | x) = \sum_{k \neq i} P(c_k | x) = \underbrace{1 - P(c_i | x)}$$

NB:

- reject option might require human ~~assist~~ analysis
- or another ML algorithm

Decision:

- choose  $C_i$   $\min_{1 \leq i \leq K} R(d_i | x)$

output:  $P(c_i | k) > P(c_k | x)$

- $C_i$  if  $P(c_i | x) > 1 - \lambda$

- Reject otherwise

Cases:

$$\lambda = 0$$

"always reject"  
(as good as correct classification)

$$\lambda = 1$$

"never reject"  
(as bad as incorrect classification)

NB:

$$\lambda \underbrace{\sum_{k=1}^K P(c_k | x)}_1$$

via complement rule (i.e. one minus "doing it correctly")

# Discriminant Functions

- Choose  $g_i(x)$ ,  $i=1, \dots, k$  s.t. output  $C_i$  if  $g_i(x) = \max_k g_k(x)$

- Bayes' Classifier:  $g_i(x) = -R(d_i|x)$

- 0/1 loss:  $g_i(x) = P(C_i|x) = \frac{P(x|C_i)P(C_i)}{P(x)}$  via Bayes' Rule

Equivalent way:  $g_i(x) = P(x|C_i)P(C_i)$  (simpler/easier)

- $k$  decision regions

$$R_i = \{x \mid g_i(x) = g_k(x)\}$$

## $k=2$ classes

- Dichotomizer ( $k=2$ ) vs Polychotomizer ( $k>2$ )
- $g(x) = g_1(x) - g_2(x)$

$$\text{choose } \begin{cases} c_1 & \text{if } g(x) > 0 \\ c_2 & \text{otherwise} \end{cases}$$

- Log odds:

$$\log \frac{P(c_1 | x)}{P(c_2 | x)} = \underbrace{\log P(c_1 | x) - \log P(c_2 | x)}_{\text{log difference in probabilities}}$$

# Bayesian Thinking Revisited

# Introduction to Bayes Factors

## • Return to HIV testing

•  $H_1$ : Patient does not have HIV

•  $H_2$ : Patient does have HIV

## • Actions/Decisions

•  $d_1$ : Choose  $H_1$

•  $d_2$ : choose  $H_2$

•  $L(d)$  the loss associated w/ decision  $d_i \forall i \in \{1, 2\}$

•  $d = d_1$

– Right: decide  $H_1$  / and they don't  $\Rightarrow L(d_1) = 0$

– Wrong: decide  $H_1$  / and they do  $\Rightarrow L(d_1) = \omega_1$

•  $d = d_2$

– Right: decide  $H_2$  / they do  $\Rightarrow L(d_2) = 0$

– Wrong: decide  $H_2$  / they don't  $\Rightarrow L(d_2) = \omega_2$

NB: notes based  
on chp. 3 Losses  
and Decision Making  
An Introduction to Bayesian  
Thinking

Losses

$$L(d_1) = \begin{cases} \emptyset & \text{if } d_1 \text{ correct} \\ w_1 = 1000 & \text{else} \end{cases}$$

$$\left\{ \begin{array}{l} H_1: \text{Patient } \overset{\text{does not}}{\text{have}} \text{ HIV} \\ H_2: \text{Patient has HIV} \end{array} \right.$$

$$L(d_2) = \begin{cases} \emptyset & \text{if } d_2 \text{ correct} \\ w_2 = 10 & \text{else} \end{cases}$$

Posteriors

- (+) stands for a positive result from the ELISA
- $P(H_1 | +) \approx 0.88$  posterior prob. of NOT having HIV given a (+) ELISA result
- $P(H_2 | +) \approx 0.12$  Posterior prob. of Having HIV given the (+) ELISA result (from the complement)

## Expected Losses

13

- $E(L(d_1)) = 0.88(\emptyset) + 0.12(1000) = 120$

$$E[L(d_2)] = 0.88(10) + 0.12(\emptyset) = 8.8$$

- Since  $E[L(d_2)] < E[L(d_1)] \Rightarrow$  decide the patient has HIV

NB:

- Decision highly influenced by losses assigned to  $d_1$  and  $d_2$

- If losses symmetric, say  $w_1 = w_2 = 10$

- $E[L(d_1)] = 0.88(\emptyset) + 0.12(10) = 1.2$

- While  $E[L(d_2)]$  would not change

- We would decide that patient does NOT have HIV!

## Bayes factors

- Continue with HIV testing example

- Prior odds = ratio of the prior probabilities of hypotheses

$$O[H_1 : H_2] = \frac{P(H_1)}{P(H_2)}$$

- Posterior odds = ratio of the two posterior probabilities of hypotheses

$$PO[H_1 : H_2] = \frac{P(H_1 | \text{Data})}{P(H_2 | \text{Data})}$$

Using Bayes' Rule, we find that

$$PO[H_1 : H_2] = \frac{P(H_1 | \text{Data})}{P(H_2 | \text{Data})}$$

$$= \frac{P(\text{data} | H_1) P(H_1) / P(\text{data})}{P(\text{data} | H_2) P(H_2) / P(\text{data})}$$

$$= \frac{P(\text{data} | H_1) P(H_1)}{P(\text{data} | H_2) P(H_2)}$$

$$= \underbrace{\frac{P(\text{data} | H_1)}{P(\text{data} | H_2)}}_{\text{Bayes Factor}} * \underbrace{\frac{P(H_1)}{P(H_2)}}_{\text{Prior odds}}$$

So, we have that

$$PO[H_1 : H_2] = BF[H_1 : H_2] * O[H_1 : H_2]$$

- BF quantifies the evidence of data arising from  $H_1$  versus  $H_2$

- In the discrete case:  $BF[H_1 : H_2] = \frac{P(\text{data} | H_1)}{P(\text{data} | H_2)}$

(likelihood ratio)

- In the continuous case

$$BF [H_1 : H_2] = \frac{\int P(\text{data} | \theta, H_1) d\theta}{\int P(\text{data} | \theta, H_2) d\theta}$$

NB:  $\theta$  is the index of all possible models/parameters

— Continue w/ HIV case

$H_1$ : Patient does not have HIV

$H_2$ : Patient does have HIV

— Priors:

$$P(H_1) = .99852$$

$$P(H_2) = .00148$$

NB: from prevalence of HIV in the population

→ Prior odds then is

$$O[H_1 : H_2] = \frac{P(H_1)}{P(H_2)} = \frac{.99852}{.00148} = 674.6757$$

- Posteriors

$$P(H_1 | +) = .8788551$$

$$P(H_2 | +) = .1211449$$

$$PO[H_1 : H_2] = \frac{.8788551}{.1211449} = 7.254578$$

- Bayes Factor

$$\begin{aligned} BF[H_1 : H_2] &= \frac{PO[H_1 : H_2]}{O[H_1 : H_2]} \\ &= \frac{.725457}{674.6757} = 0.00108 \end{aligned}$$

$$= \frac{P(+ | H_1)}{P(+ | H_2)} = \frac{.01}{.93} \approx .0108$$

- so now that we have calculated  $BF[H_1 : H_2]$ , how should understand its meaning?

- Jeffrey (1961)

$BF[H_1 : H_2]$	Evidence against $H_2$
1 to 3	Not worth a bare mention
3 to 20	Positive
20 to 150	Strong
> 150	Very strong

$2 * \log(BF[H_1: H_2])$	Evidence against $H_1$
0 to 2	Not worth a bare mention
2 to 6	Positive
6 to 10	Strong
> 10	Very strong

- NB: notice that for the HW case it doesn't even appear on the scale.

- Let's reader so that it's  $BF[H_2: H_1] = \frac{1}{BF[H_1: H_2]} = \frac{1}{.0108} = \underline{\underline{92.59259}}$

$\approx 93$

- Hence the evidence against  $H_1$  is ~~the same~~  
"Strong"
